ABSTRACT

Over the past decades, divorce and cohabitation have increased dramatically throughout Europe. Divorce has fundamentally altered the institution of marriage from a life-long union to one that may dissolve. Cohabitation allows couples to live together without undertaking the vows of marriage, but also allows couples to avoid the potentially higher costs of divorce. Thus, divorce and cohabitation seem to be intrinsically linked. Here we theorize how the increase in divorce may be linked to the increase in cohabitation on the macro-, meso-, and micro- levels. Using focus group data from 8 countries, we explore how divorce may have changed attitudes and beliefs concerning marriage and cohabitation. We then investigate whether survey data and official statistics in 16 countries provide evidence consistent with a link. While exogenous factors have been important for the increase in cohabitation, we argue that the divorce revolution has been a catalyst for the cohabitation boom.

1. INTRODUCTION

Divorce and cohabitation are two of the largest behavioral changes to affect the family over the past few decades. Both behaviors have received substantial media and public attention around the world, with some alarmingly calling these two behaviors a “breakdown in the family.” Undoubtedly, the two behaviors have fundamentally altered the institution of marriage. The increase in divorce has changed marriage from a union intended to be life-long to a relationship that has the potential to dissolve. At the same time, cohabitation has emerged as a way for two people to live in an intimate relationship without undertaking the vows of marriage and to avoid the potentially higher costs of divorce if the union does not last. Thus, divorce and cohabitation appear to be intrinsically linked.

Current theories explaining the emergence of these new behaviors tend to either explain divorce and cohabitation separately or include them in a broader set of changing family behaviors, often referred to as the Second Demographic Transition (Sobotka 2008, Lesthaeghe 2010, van de Kaa 2001). These theories usually point to economic shifts (Becker 1991, Oppenheimer 1997, Ruggles 2015) or social and ideational change (Giddens 1992; Lesthaeghe 2010, Perelli-Harris et al. 2010) to explain the emergence of the new behaviors. While these theories are crucial for understanding the underlying factors leading to the behaviors, they have not specifically examined whether or how the increase in divorce may have been fundamental to the development of cohabitation. Given the dramatic increase in both divorce and cohabitation throughout much of the industrialized world, in this paper we argue that the divorce revolution could have been an important catalyst for the cohabitation boom.

It is important to note, however, that the relationship between divorce and cohabitation is most likely not unidirectional, but instead could flow both ways and influence each trend through feedback loops (Bumpass 1990). For example, the experience of cohabitation as a less permanent relationship may lead to greater union instability in general (Berrington and Diamond 1999, Liefbroer and Dourleijn 2006). Furthermore, the emergence of cohabitation may have led to greater selection into marriage, resulting in a decline or stabilization of divorce, as appears to have occurred in the US (Kennedy and Ruggles 2014) and UK (Beaujouan and Ni Bhrolcháin 2014). Nonetheless, while the full development of these trends may be complicated, an investigation into whether or how the increase in divorce may have led to the rise of cohabitation is warranted.

To evaluate the evidence in support of a link between divorce and cohabitation, we search for trends and mechanisms at different hierarchical levels: the macro-, meso-, and micro-. Demographers are often interested in processes which occur at the population level (the macro), but recognize the importance of decisions made at the individual level (the micro) (Billari 2015). An intermediary level between the two is the family (the meso), often referred to as the intergenerational transmission of behaviors and attitudes. Studying evidence at each of these levels may produce a different understanding of how the link between divorce and cohabitation operates, and the mechanisms through which the two are linked.

To search for evidence and mechanisms, we use “a form of bricolage, knitting together diverse strands of evidence.” (Ni Bhrolcháin and Dyson 2007: 29). For each analytical level, we first use qualitative methods to describe social discourses

surrounding cohabitation and marriage, which can elucidate potential mechanisms and provide explanations for the link. The qualitative evidence comes from focus group data collected in 8 European countries and emerged from a broader project that studied the meaning of cohabitation and marriage (see Special Collection: Focus on Partnerships in *Demographic Research 2015-16*). The issue of divorce arose in nearly every focus group, especially with respect to how cohabitation is useful as a “testing ground” to avoid divorce (Perelli-Harris et al 2014). Below we provide additional analysis of the focus group materials to better understand how people think about the link between divorce and cohabitation.

We then analyze quantitative data to see whether any evidence supports the idea that the increase in divorce fuelled the increase in cohabitation. We draw on official sources and harmonized partnership histories based on surveys conducted in 16 countries in Europe. Since cohabitation was not collected in population registers before the 2000s, nationally-representative surveys are the only source of detailed cohabitation histories dating back several decades, and thus are the best available data. We also include information on legal reform; changes in the legal availability of divorce were important for facilitating the increase in divorce. Although the analyses we perform are not exhaustive and insufficient to conclusively demonstrate causality, they provide insights into whether the evidence is consistent with a direct link between divorce and cohabitation. Given that cohabitation has different meanings in different countries (Perelli-Harris et al 2014, Hiekel et al 2014), we expect that the relationship between divorce and cohabitation will be more evident in some countries than in others. In addition, we acknowledge that cohabitation has heterogeneous meanings across individuals, strata, and at different stages of the lifecourse (Perelli-Harris and Bernardi

2015). While we do not interrogate these meanings here, we believe that the divorce revolution has the potential to encourage cohabitation across a range of types, for example as a precursor or an alternative to marriage (Kiernan 2004, Heuveline and Timberlake 2004).

Finally, we synthesize our findings to explain how the increase in divorce may have been one (among many) of the factors leading to the increase in cohabitation. Drawing on previous studies and our results, we elucidate mechanisms at each analytical level. We argue that divorce may have led to the adoption of cohabitation through the diffusion of new social norms and values about marriage, the process of social learning from parents who divorced, and the personal experience of divorce. Taken together, this study provides a new way of thinking about the development of cohabitation.

2. DATA

2.1. QUALITATIVE DATA

The focus group project as a whole was motivated by an interest in better understanding the increase in cohabitation throughout Europe. Although quantitative research had explored the development of cohabitation cross-nationally, little was known about how people discussed cohabitation and marriage in different countries. The goal of focus group research is not to provide representative data, but to understand general concepts and substantive explanations for social phenomena. Thus, focus group research allows the researcher to fill gaps in knowledge, generate research hypotheses, and propose avenues for new quantitative research (Morgan 1998), as we do below.

For the Focus Group project, collaborators conducted 7-8 focus groups in the following cities: Vienna, Austria (Berghammer et al 2014), Florence, Italy (Vignoli and Salvini 2014), Rotterdam, the Netherlands (Hiekel and Keizer 2015), Oslo, Norway (Lappegard and Noack 2015), Warsaw, Poland (Mynarska et al 2014), Moscow, Russia (Isupova 2015), Southampton, United Kingdom (Berrington et al 2015), and Rostock and Lubeck, Germany (Klärner 2015). The chosen countries represent a range of welfare-state regimes and historical family systems in Europe. Each focus group comprised 8-10 participants, with a total of 588 participants across Europe. The focus groups followed a standardized guideline (see Perelli-Harris et al 2014) ensuring that each group discussed the same topics. The researchers transcribed the results in the native language of their countries, coded the results according to a standard procedure and produced a country report in English that covered general topics. The collaborators then wrote an overview paper, which synthesized the main findings of the project (Perelli-Harris et al 2014), as well as articles on each country. For the analysis below, we use the overview paper and the country reports, but we also asked each country team to revisit the transcripts and report on themes relating to the role of divorce in changing patterns of marriage and cohabitation.

2.2. QUANTITATIVE DATA

To assess the relationship between the diffusion of divorce and cohabitation with quantitative data, we evaluate several sources: official statistics, survey data, and changes in divorce legislation. The official statistics were compiled in the Divorce Atlas and show the Total Divorce Rate (TDR) (Spijker 2012). The TDR is “the mean number of divorces per marriage in a given year, or the divorce rate of a hypothetical generation subjected at each marriage duration to current marriage conditions” and can show

period response to changes in policy. The individual survey data is based on female retrospective union histories from 16 surveys standardized in a dataset called the Harmonized Histories (Perelli-Harris et al. 2010, and see www.i-ggp.org). Because men's histories were not available in all surveys, we only show women's experiences. The data come from nationally representative Generations and Gender Surveys (GGS) for the following countries (year of survey in parentheses): Belgium (2008-10), Bulgaria (2004), the Czech Republic (2004-6), Estonia (2004-5), France (2005), Hungary (2004-5), Italy (2003), Lithuania (2006), Norway (2007-8), Poland (2010-11), Romania (2005), Russia (2004), and Sweden (2012-13). Because the GGS is not available for all countries (or the retrospective histories were not adequate for our purposes), we also used other data sources: the Dutch 2003 Fertility and Family Survey; the British Household Panel Survey (1991-2008) and the 2006 Spanish Survey of Fertility and Values. The surveys that comprise the Harmonized Histories have been frequently used in other studies and are generally considered high quality. In particular, fertility and marriage trends from most of the Generations and Gender Surveys reflect trends found in vital registration statistics (e.g. Vergauwen, Wood, and Neels 2015). Some countries such as the Netherlands only interviewed respondents of reproductive age, limiting the historical period we could analyze. Although we investigated using earlier Fertility and Family Surveys for some countries, the age range surveyed (15-49) and the numbers at older ages did not allow for additional analyses.

2.3. DIVORCE LEGISLATION REFORM

In addition to analyzing qualitative and quantitative data, it is also important to recognize when divorce laws developed in Europe over the past decades. The timing and extent of divorce reforms has differed across countries. Changes in the legal

availability of divorce, as well as reforms of divorce requirements and procedures, facilitated the deinstitutionalization of marriage by allowing couples to dissolve a marriage if it no longer provides mutual benefits (Lewis, 2002; Cherlin, 2004). Divorce law allows us to better understand differences in family contexts, and how they relate to the increase in cohabitation. To facilitate the analysis of divorce reform, we present Table 1, which provides an overview of the dates of important divorce reforms in selected European countries. We distinguish between dates when: divorce first became available; procedures became available for mutual-consent divorce; no-fault divorce procedures simplified divorce; and other reforms changed divorce procedures. These different types of reform – fault-based divorce, divorce in case of marriage breakdown, and divorce by mutual consent – are not mutually exclusive. Generally, different types of divorce have been available within the same jurisdictions at different points in time (Martiny 2004).

Note that couples can also separate without officially divorcing. Indeed, some of the earliest increases in cohabitation could have occurred because individuals were unable to legally divorce and wanted to live with a new partner (Burgoyne 1991, Kiernan and Estaugh 1993, McRae 1993). This earlier period of post-separation cohabitation, however, was not widespread; we argue that only when divorce became legal and socially sanctioned did marital dissolution foster the increase in cohabitation. Nonetheless, the distinction between legal divorce and separation are elided in many datasets; for example, survey questions ask respondents whether their parents lived together in childhood rather than asking specifically about marital status. In reality separation and divorce can also be blurred, since divorce is usually a process that includes separation and can last for years. Thus, below we primarily use the word

divorce, but imply the general process of marital dissolution because the definition is ambiguous in some of the datasets.

	Introduction of divorce	Introduction of non-fault divorce	Introduction of divorce by mutual consent	Dates of other divorce law reforms
Belgium	Before 1950	Before 1950	Before 1950	1975, 1982, 1994, 1997, 2000, 2007

3. MACRO-LEVEL LINKS: THE INCREASE IN DIVORCE AND THE DIFFUSION OF COHABITATION

Theories of the family often claim that the increase in divorce and cohabitation are part of the same package of family behavior, emerging due to economic and social change.

Women’s increasing labor force participation and men’s eroded position in the labor force have changed the marital bargain: as spouses began to resemble each other and gains from specialization are reduced, the value of marriage has deteriorated with divorce becoming a more advantageous option for some (e.g. Becker 1991). Women’s increased autonomy has also allowed women to postpone marriage and choose cohabitation as an attractive alternative (Oppenheimer 1997, Oppenheimer, Kalmijn et al. 1997, Kalmijn 2011). The economic uncertainty and inequality that increased throughout the last decades of the 21st century due to globalization (Blossfeld et al 2006) exacerbated these trends: in many countries, individual-level economic uncertainty is associated with union instability (Amato and James 2010), as well as

cohabitation and childbearing within cohabitation, particularly among the least educated (Perelli-Harris et al 2010, Hiekel et al 2014). More broadly, social and ideational liberalization (Giddens, 1992; Lesthaeghe 2010), led to greater emphasis on individualization and personal fulfilment and reduced the influence of institutions such as religion (Lesthaeghe and Surkyn 1988). Finally, the contraceptive revolution may have facilitated these developments by separating sex from reproduction, liberalizing sexual norms and supporting feminism (Westoff and Ryder 1977). Hence, we recognize that many ideational and economic factors that are exogenous to the divorce-cohabitation link may have independently led to the rise of both behaviors.

Nonetheless, the increase in divorce itself could have been one of the social changes that exacerbated the increase in cohabitation. To explain the link at the macro-level, we draw on diffusion theory, which has frequently been used to explain how the spread of new attitudes and behaviors led to the decline in fertility (Casterline 2001). Diffusion theory posits that changes in behavior occur through behavioral innovation, ideational change, and social dynamics (Casterline 2001). Using the diffusion framework, we argue that the increase in divorce is a relatively new social phenomenon that changes attitudes and spreads throughout social networks. This unprecedented, widespread prevalence of divorce fundamentally alters social norms about the permanency of marriage, leading to the deinstitutionalization of marriage (Cherlin, 2004; Lewis, 2002). Marriage is then no longer perceived as an automatic way of organizing family life, but instead becomes more tenuous and uncertain. The relaxation of divorce laws with the implementation of no-fault and mutual consent divorce reinforces the idea that divorce is acceptable and marriages can end. Cohabitation then arises as a response to the new marriage reality and becomes an acceptable alternative

living arrangement, particularly as a means of testing the relationship to ensure it is strong enough for marriage (McRae, 1993, Perelli-Harris et al 2014, Hiekel and Keizer 2015). Thus, the diffusion of new attitudes about divorce and consequently the changing meaning and value of marriage allow for the expansion of a new innovative behavior - cohabitation.

3.1. MACRO-LEVEL EXPLANATIONS AND MECHANISMS FROM QUALITATIVE RESEARCH.

Qualitative research has helped to elucidate this argument by providing further details. Previous U.S. in-depth interview research found that individuals refer to a “fear of divorce” that leads them to be wary of the institution of marriage or to have doubts about marrying a particular individual (Miller et al. 2011). Qualitative evidence from the early 1990s in the UK also suggested that cohabitation emerged as a testing ground in response to divorce (McRae 1993). In our European focus group research, participants in nearly every country seemed to have an awareness of the link between divorce and cohabitation at the macro-level: they stated that the increase in divorce and partnership instability was one of the main reasons for the increase in cohabitation. In the Netherlands, this theme was so pervasive that Hiekel and Keizer (2015) argued that cohabitation was a strategic response to high marital instability. For example, this Dutch respondent states:

“Perhaps it is our generation that is brought up with the idea that [marriage] often goes wrong, that that is a catalyzing factor ...this is of course not the initial factor why people start living together unmarried. But if it [marriage] goes wrong more often, you might think “well, I’d better not risk a failure, because I will experience a lot of negative consequences.””

Participants from the UK focus groups also articulated an awareness of how high divorce rates may discourage marriage at the macro-level, for example;

“I wonder if there’s something about the kind of way it’s portrayed in statistics...you’re kind of told about high levels of divorce and marriages which break down and things, so I wonder if there’s perhaps something about putting people off going through that process, if there’s a potential that there might not be a happy ending maybe.”

These types of responses indicate a general sense that marriage is no longer seen as a long-term, binding union; divorce has eroded the permanence of marriage. Some described a lack of confidence in marriage, as this UK respondent said, “I don’t think people have got as much faith in marriage either anymore... It’s not a forever thing anymore, is it, whereas before it was more of a commitment than nowadays.” For some, the disillusionment with marriage led to a rejection of marriage altogether. In most countries, a few participants saw marriage as little more than a piece of paper.

At the same time, however, participants in most countries did express the opinion that marriage was still a sign of a committed relationship. As discussed in Perelli-Harris et al (2014), in all of the countries examined, marriage was seen as valuable, with the exception of eastern Germany where it was seen as less relevant. The high value placed on marriage results in people wanting to test their relationship with cohabitation to ensure it is solid enough for marriage and to avoid divorce. Thus, the meaning of cohabitation as a “testing-ground” was one of the main findings of the comparative paper (Perelli-Harris et al 2014). Cohabitation allows couples to ensure they are compatible and to avoid the costs and consequences of divorce. The qualitative evidence suggests that in some countries, for example Norway, living together before

marriage has become normative, with marriage reserved for later in the lifecourse, sometimes as a celebration of surviving the period with young children (Lappegard and Noack 2015).

In all countries, focus groups participants perceived cohabitation as easier to dissolve than marriage, although in some cases children and mortgages could make a cohabiting partnership difficult to disentangle. Nonetheless, the costs of divorce were almost always perceived as higher than the costs of dissolving a cohabiting union. In Italy, one participant stated:

“Divorce is a complex, long, and expensive thing. So, although the couple is unhappy, you may be forced to remain together. By contrast, putting an end to a cohabiting union is much faster.”

Throughout the focus groups, participants discussed several types of costs: psychological, emotional, social, financial, and bureaucratic. In the Netherlands, one participant expressed the opinion that divorce would be “some kind of failure in public;” in Poland, some felt that those who divorced were labelled as a “divorcee;” and in Italy “divorce essentially means many psychological costs.” However, the focus group participants agreed that divorce rarely incurred the same social stigma as it did in the past. Instead, participants were more likely to point out the financial and legal or bureaucratic costs of divorce. This ranged from muttering about the “fuss” involved in changing names and legal documents to complaining about the substantial expense and time to divorce. The magnitude of the costs seemed to depend on legal setting. In Italy, participants in several focus groups mentioned the economic fear of divorce as well as

the extensive court trials and long waiting periods. In Germany, this man described his brother's divorce:

“That was a real ordeal, it took forever, with all this red tape and not keeping appointments and who knows what. A break-up is mean and nasty already for everyone involved. But a divorce is way worse.”

In Austria, one man even expressed a fear of marriage, because of the high consequences of divorce:

“This is maybe not the most important point but everyone that has witnessed a divorce that took some years, that is a bit scary. It is scary to risk the step towards marriage.”

In some countries, the participants pointed out that the men had to disproportionately bear the costs of divorce and in the process lose much of what they owned. As one Austrian man stated,

“For men, with respect to the law, it is not very advantageous to marry...The women and children get the flat plus maintenance...From the man's point of view, it does not pay off to marry.”

As one eastern German man put it,

“People have become more cautious, it is not for nothing that one says: marry in haste, and repent at leisure. And then you can see what men sometimes have to endure and how much money they have to pay in a divorce. One should not get married before having the money for the divorce.”

To summarize, our analysis has shown how the general awareness and wariness of divorce in our studied countries has permeated throughout society and is a key factor leading to an increase in cohabitation at the macro-level. Divorce has eroded some peoples' faith in marriage, leading them to eschew marriage altogether. At the same time, however, most participants still value marriage and want to avoid the high costs and consequences of divorce. Thus, cohabitation, which is usually easier to dissolve, plays an important role as a testing ground before marriage as a way of avoiding divorce.

3.2. MACRO-LEVEL ANALYSES WITH QUANTITATIVE DATA

Establishing the divorce-cohabitation link at the macro-level is particularly difficult without falling prey to the over-interpretation of observed correlations due to exogenous factors, such as female employment or ideational change. Nonetheless, examining basic trends is useful for showing how the two behaviors developed and seeing whether these qualitative discourses might be reflected in macro-level data. When evaluating the quantitative data, we consider several criteria supportive of causal inference, but we primarily focus on temporal ordering (Ni Bhrolchain and Dyson 2007). At bare minimum, if increasing divorce rates lead to increasing levels of cohabitation, the rise in marital dissolution must occur first.

To explore the evidence that the increase in divorce preceded the increase in cohabitation on the macro-level, we compare three different indicators in Figures 1a-1c. Two of the indicators measure the increase in divorce, while one represents the general level of cohabitation in each country. The dark solid line represents the Total

Divorce Rate (TDR) and captures period “shocks” in divorce, for example due to changes in divorce law or economic conditions which may have curtailed divorce. In most countries, the TDR steadily increased throughout the period of observation, but it also reflects strong responses to divorce reform and socio-economic change, for example in Russia, Estonia, Lithuania, and Spain.

The black dashed line, compiled from retrospective partnership histories, shows the percent of women who have ever experienced marital dissolution among all ever married women aged 30-49. This line represents the stock of those who ever divorced, or the share of the ever divorced in the general population. The grey line, also based on retrospective partnership histories, shows the percent of women aged 20-49 in a cohabiting relationship among those in partnership in a given year¹. This indicator shows how common cohabitation is during any given period. Note that we are specifically interested in the decision to cohabit or marry for those in a partnership; the increase in divorce may have led to the delay or avoidance of co-residential unions, but we are less interested in the decision to remain single and more interested in whether people chose cohabitation over marriage. The trend lines start and end in different years in each country, because each survey year was different and each survey interviewed different age ranges and may not have interviewed sufficient numbers of older women to make meaningful estimates for earlier years. To ensure sufficient numbers of women, each line starts in the year in which each age group includes at least 50 women. We only show women up to age 50; although we would have liked to have included women who experienced divorce later in life, the age 50 cut-off allows us to look further back in time. Even with this age constraint, some countries still had only relatively short

¹ The percentages were estimated in January of a given year. Weights have been applied if available.

trend lines (e.g. in Belgium the trend line only starts in 1994, because insufficient women at older ages were interviewed). The figures also show the year (a vertical dashed grey line) in which divorce law reforms were enacted (see also Table 1),² in order to demonstrate when divorce became legal or reforms were enacted which facilitated divorce.

² Note that other types of reforms, such as changes in the waiting period for divorce, may have led to a strong increase in the Total Divorce Rate. For example, the steep increase in the Total Divorce Rate in Spain was due to a 2005 reform (see Table 1) which eliminated the period of de facto separation.

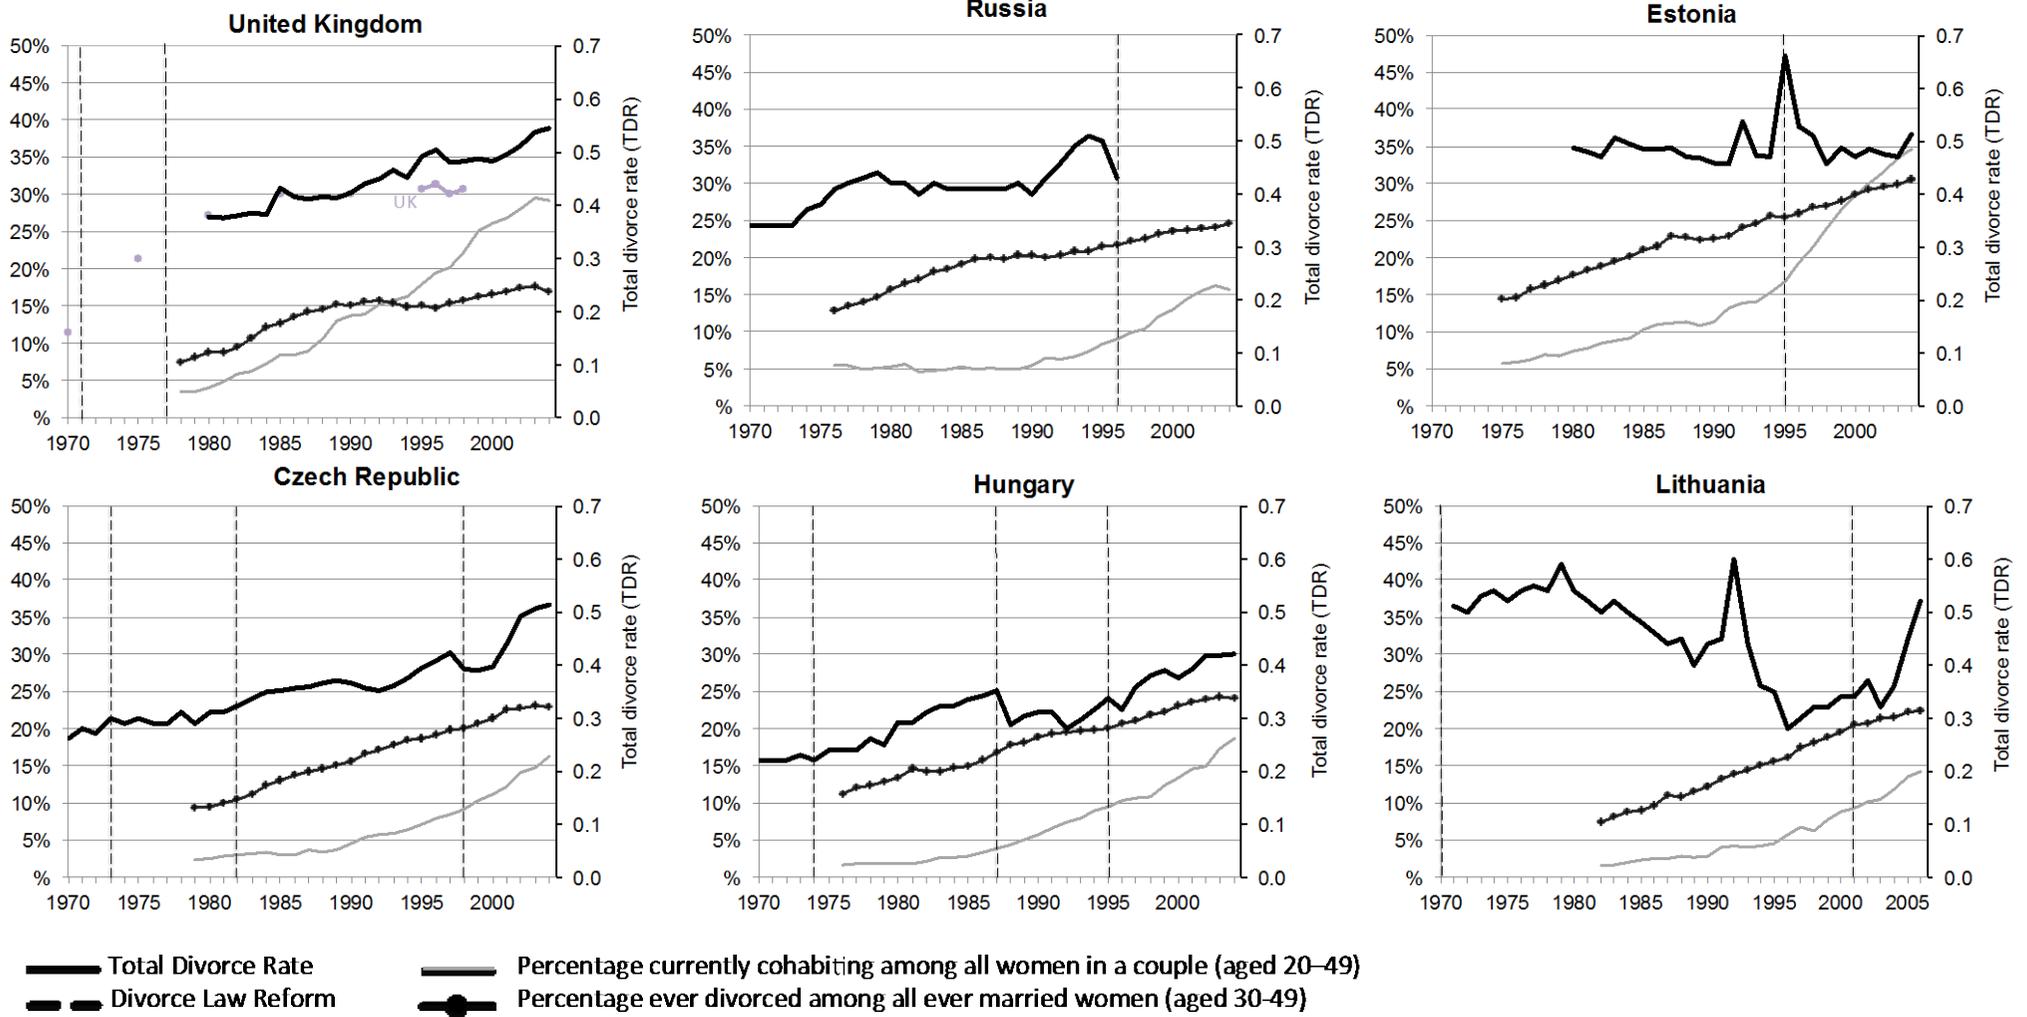

Figure 1a: Total Divorce Rate, % ever divorced women among ever married women (age 30-49), currently cohabiting women among all couples (age 20-49), and Year of implementation of divorce reforms, in Group a: Divorce initially high and steadily increasing - Cohabitation initially low, then increasing at faster pace than divorce.

Note: weights applied if available.

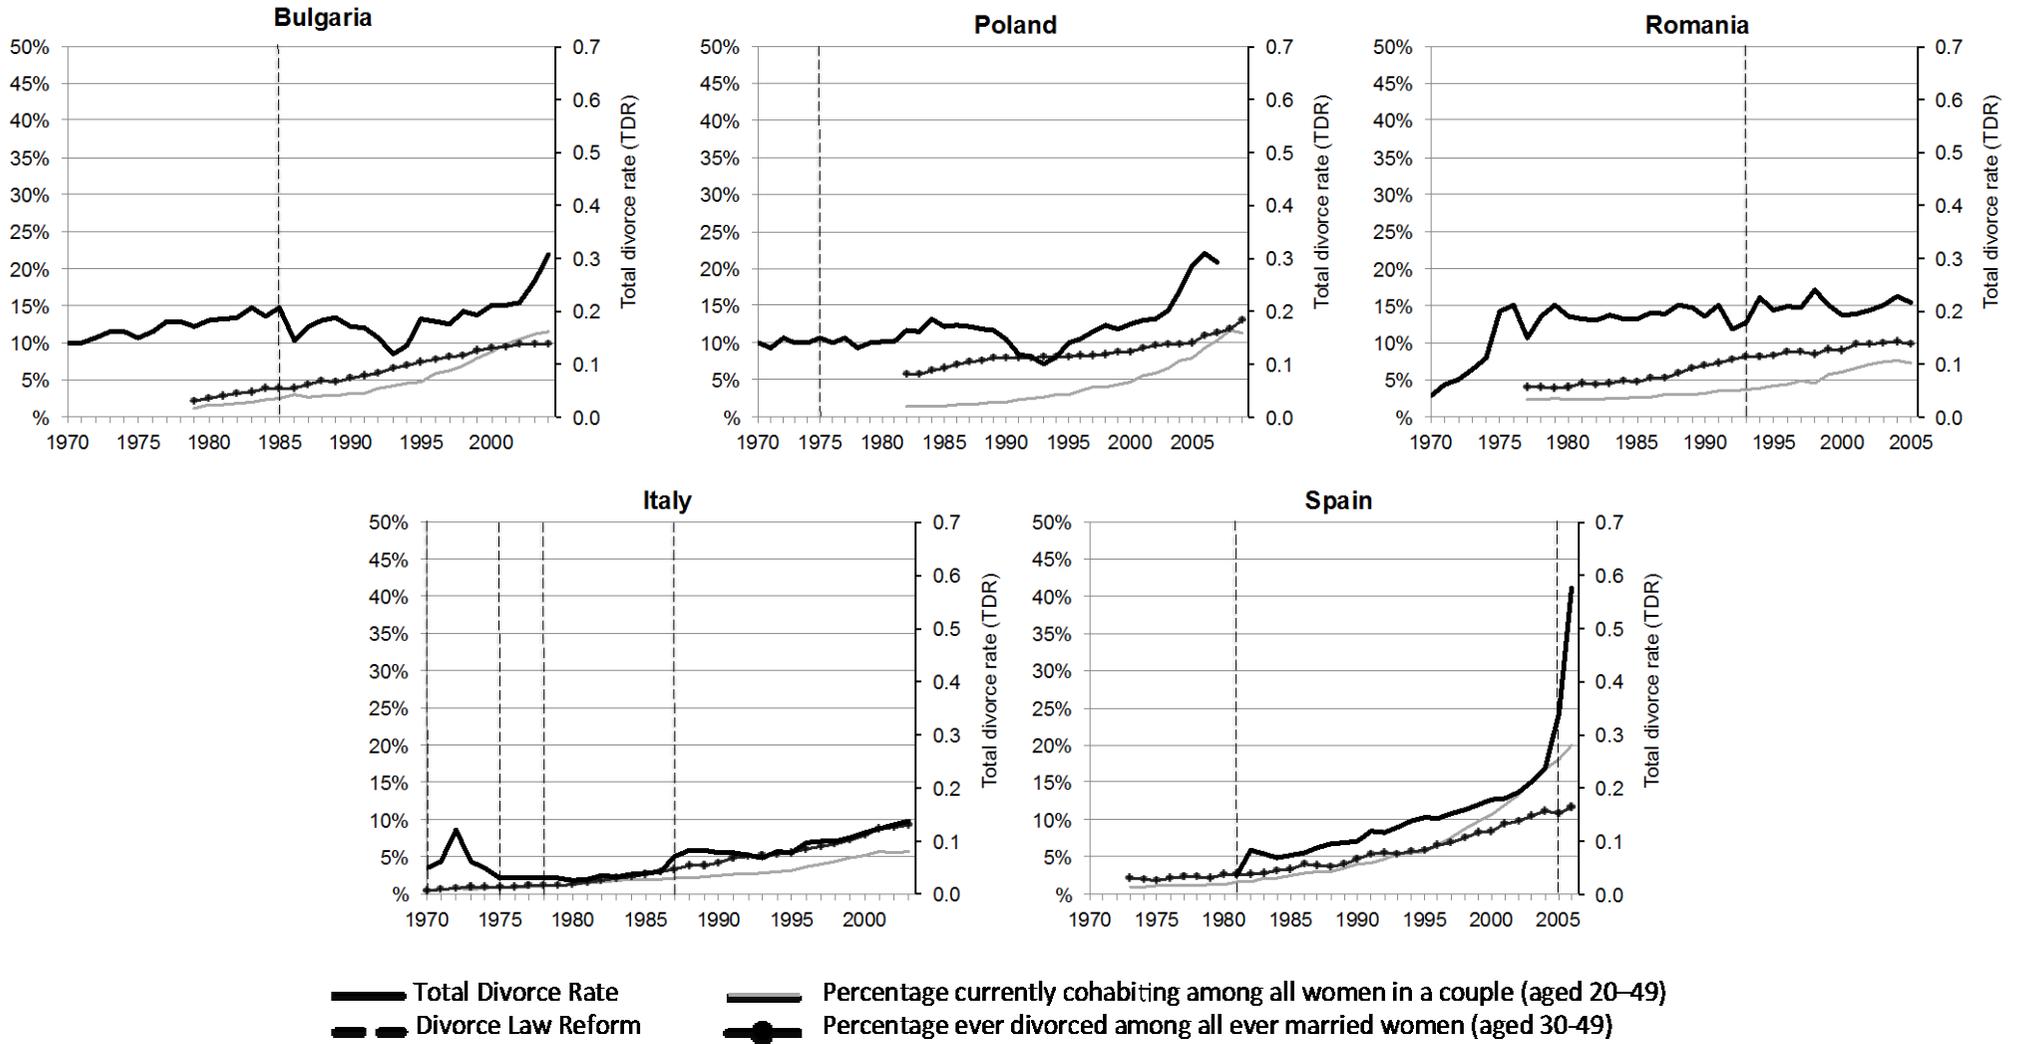

Figure 1b: Total Divorce Rate, % Ever divorced women among ever married women (age 30-49), Currently cohabiting women among all couples (age 20-49), and Year of implementation of divorce reforms, in Group b: Divorce initially low, then slowly increasing – Cohabitation initially low, increasing since 1990s/2000s.

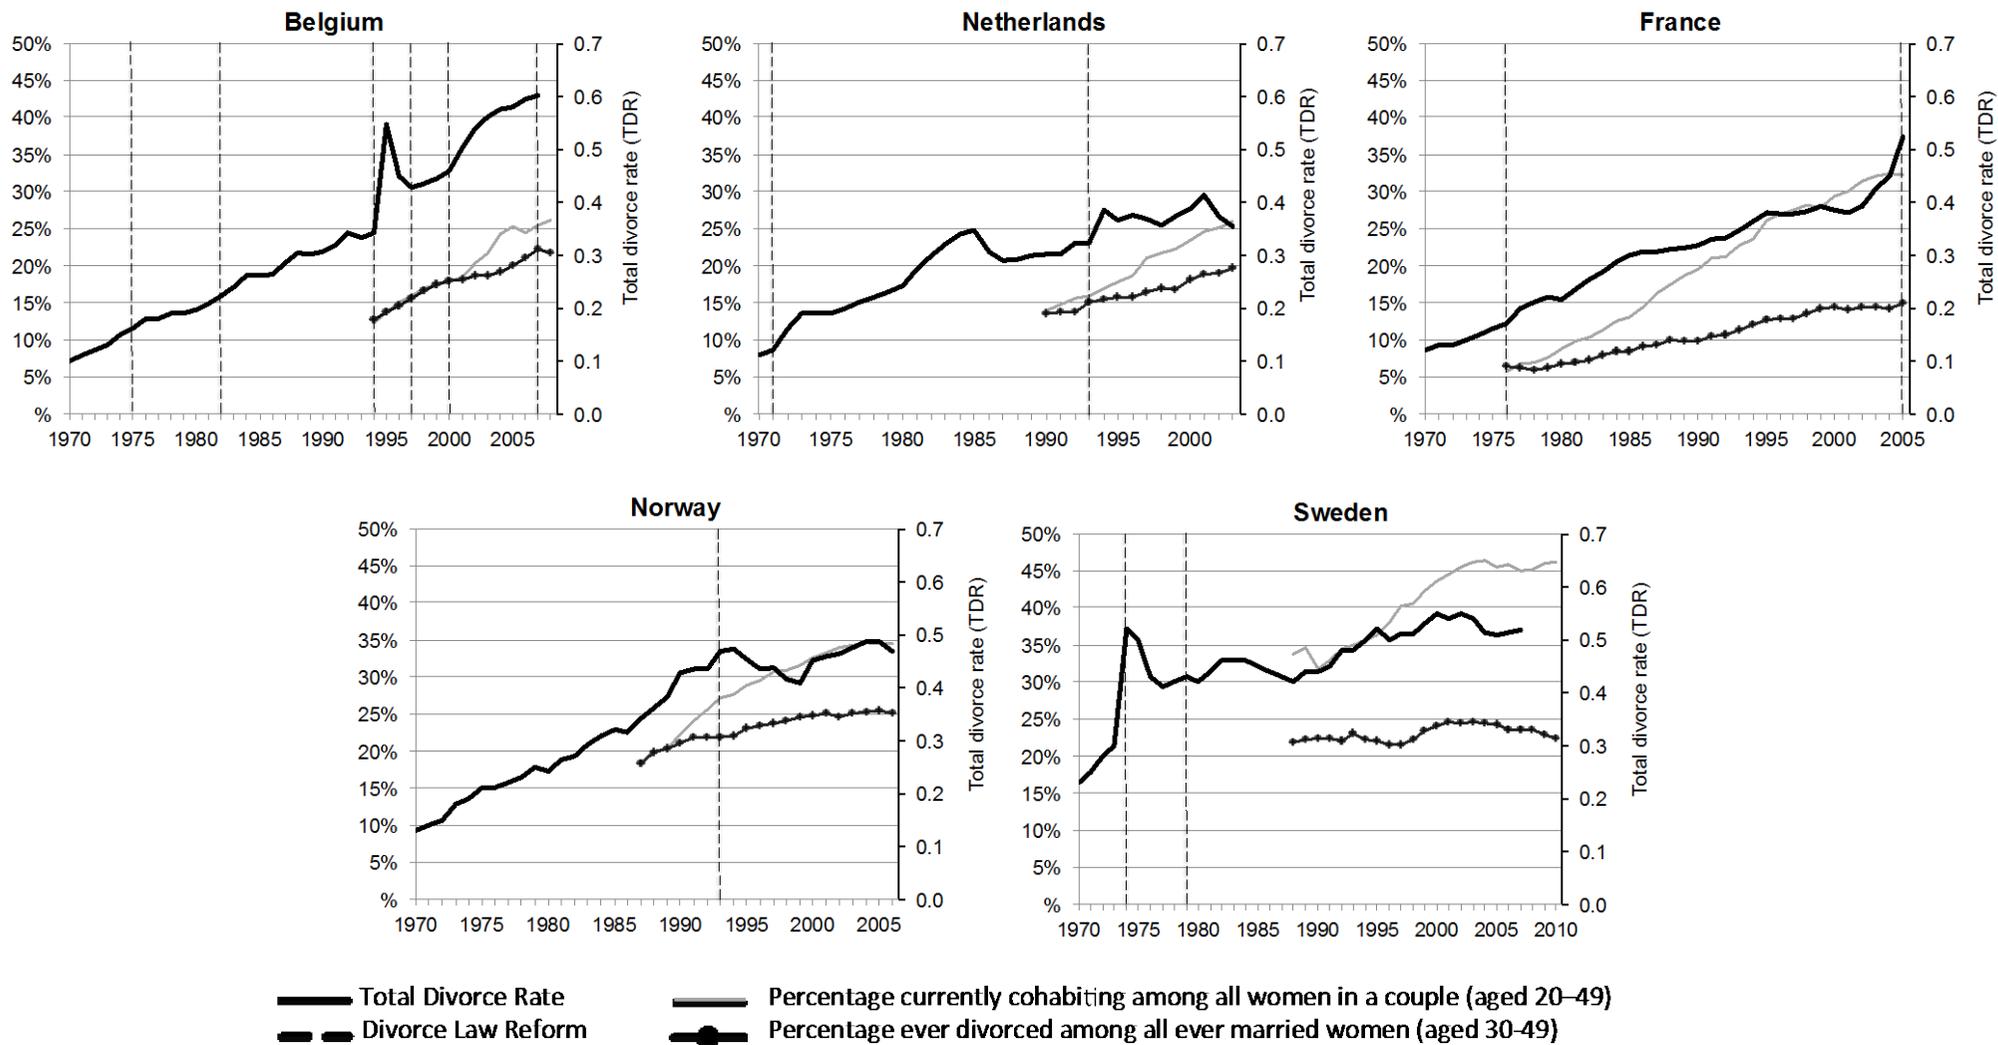

Figure 1c: Total Divorce Rate, % ever divorced women among ever married women (age 30-49), currently cohabiting women among all couples (age 20-49), and Year of implementation of divorce reforms, in Group c: Divorce and cohabitation initially as similar levels – Cohabitation then outpacing divorce.

In all the countries, the increase in divorce preceded or started at roughly the same time as the increase in cohabitation. However, the link is more evident in some countries than others, and we cluster the countries into several general patterns reflecting the strength of the link. The first two groups shown in Figures 1a and 1b represent countries where the quantitative data are most supportive of a potential causal link between the rise in divorce and the rise in cohabitation. In Group a, divorce rates were already quite high by the 1970s and steadily increased thereafter. Cohabitation was initially low but then increased at a faster pace than divorce. For example, the graph for the United Kingdom (Figure 1a) shows an increase in the Total Divorce Rate³ over time, and the grey dots for the UK in 1970 and 1975, the only data available, suggest that divorce increased rapidly throughout the 1970s. The black dashed line, based on partnership histories from the British Household Panel Survey, show a similar pattern, with the percent of ever married women who ever experienced divorce already increasing in the late 1970s. The percent of partnered women living in cohabitation started to increase only in the early 1980s (grey line), supporting the argument that the rise in divorce preceded the increase in cohabitation. Nonetheless, the percent of ever divorced women levelled off in the late 1980s, while the percent cohabiting continued to increase throughout the 1990s. The stabilization of divorce coupled with the increase in cohabitation may indicate that marriage is becoming more selective of stable relationships less likely to end in divorce (Beaujouan and Ni Bhrolcháin 2014, Berrington and Diamond 1999).

Many of the post-Socialist countries - Russia, the Czech Republic, Hungary, Estonia, and Lithuania also represent a situation in which divorce was initially high and steadily

³ The longer TDR line only includes England and Wales, while the short line shows the TDR for the UK as a whole.

increased, and cohabitation was initially low, then increased at a faster pace than divorce (Figure 1a). In these countries, the Total Divorce Rate was already relatively high – above 0.2 – before the beginning of the observation period. In Russia, the TDR was above 0.3 in 1970, while in Lithuania it was closer to 0.5. In all four countries, the TDR stayed relatively high or increased, although in Lithuania the TDR decreased substantially, albeit with some very short-term peaks throughout the 1990s. Thus, divorce and cohabitation increased in parallel during the 1970s and 1980s, but from the late 1990s, cohabitation accelerated in all four countries. All in all, the evidence is consistent with the expectation that the increase in divorce facilitated the increase in cohabitation.

The next set of countries in Eastern (Bulgaria, Poland, and Romania) and Southern Europe (Spain and Italy) represent cases in which divorce was initially low, then slowly increased, while cohabitation increased more rapidly since the 1990s and 2000s (Figure 1b). These countries have maintained traditional family values and tend to be more religious (Reher 1998; Vignoli and Salvini 2014; Mynarska et al 2014); only recently have family behaviors started to change (Lesthaeghe 2010). In all five countries, the TDR hardly increased above 0.2, except for a slight increase to about 0.3 in the most recent years in Bulgaria and Poland and a sharp increase to nearly 0.6 in Spain in 2005 after a reform in the divorce law, which allowed divorce without a period of previous separation. Cohabitation also remained low; the proportion of partnered women aged 20-49 who were cohabiting remained below 5% until the 2000s when it increased, and the increase was especially rapid in Spain. Thus, even though these countries experienced only a moderate increase in the two behaviors until recently, divorce does seem to have increased in parallel with the rise in cohabitation, or potentially beforehand.

The final group - Belgium, the Netherlands, France, Norway, and Sweden - shows more mixed results (Figure 1c). In all five countries, the TDR was below 0.2 in 1970 and sharply increased to above 0.4 by the late 1990s and early 2000s, indicating that these countries currently have high levels of divorce. At the same time, cohabitation increased rapidly, with the rate of acceleration more rapid than for divorce; by the mid-2000s the percentage of coupled women aged 20-49 who were cohabiting was over a third in Belgium and the Netherlands, closer to a half in France, and Norway, and over 60% in Sweden. While we know that the rate of increase in cohabitation has often been faster than the rate of increase in divorce in these countries, the lack of comparable data on cohabitation during the 1970s and 1980s means that we cannot tell whether the increase in the percent who ever divorced increased earlier than the percent in a cohabiting union. Earlier surveys from Norway suggest that cohabitation was relatively rare in the 1970s, but increased rapidly throughout the 1980s (Noack 2001); thus it is plausible that divorce levels rose first. In Sweden, however, the percent cohabiting was already relatively high in 1975, especially as a precursor to marriage (Bernhardt 1998). Data from the 1992 Swedish Family Survey shows that in 1975, 71% of women in unions aged 20-24 were cohabiting, but this percent declined to 15% for 30-34 year olds and eventually most people did marry (Bernhardt 1998). Again, because divorce rates were relatively high in Sweden, especially after the 1970 reforms, it is likely that the two behaviors started to increase in parallel. Nonetheless, cohabitation continued to increase while divorce rates stabilized, suggesting that cohabitation developed for other reasons. In France, unlike the countries shown in figures 1a and 1b, the increase in divorce over time has been less pronounced, whereas cohabitation increased rapidly, suggesting that cohabitation may have developed independently of divorce. Thus, both the Swedish and French data suggest that cohabitation increased at a much faster rate than divorce and most likely developed for different reasons.

Despite the differences in union formation behavior across our study countries, our results suggest that the initial increase in divorce preceded the increase in cohabitation in all countries for which we have data for a sufficiently long period. The increase in the TDR always occurred before the increase in the percent currently cohabiting among those in a couple, i.e. it increased to above 0.2 before the percent currently in cohabitation among those in a couple reached 10%, although both increases seemed to have occurred simultaneously in Spain. Nonetheless, the indicator for the percent ever divorced does not always seem to have a straightforward relationship to the percent currently cohabiting. In some countries cohabitation increased at a faster rate than divorce, as in France and Sweden, and more recently in Spain. Unfortunately, we do not have focus group data for these countries to see whether the explanations for the increase in cohabitation were substantially different from our other countries. In any case, however, this evidence for a macro-level link between divorce and cohabitation seems to be stronger in some countries than others.

4. MESO-LEVEL LINKS: THE INTERGENERATIONAL TRANSMISSION OF DIVORCE TO COHABITATION

In many countries, studies have found that the experience of parental divorce is a strong predictor of children's divorce (e.g. Amato 1996; McLanahan and Sandefur 1994; Wagner and Weiß 2006; Dronkers and Härkönen 2008, Wolfinger 2005) and children's cohabitation (e.g., Axinn and Thornton 1992; Axinn and Thornton 1996; Amato 1996; Bumpass, Sweet and Cherlin 1991; Thornton 1991; Berrington and Diamond 2000; Liefbroer and Elzinga 2012; Wolfinger 2005). Parent's marital break-down can change children's attitudes and decisions about relationships through a process of social learning (Cui and Fincham 2010; Smock et al 2013) and socialization (Axinn and Thornton 1996). The experience of parental divorce may lead children to be more accepting of alternatives to life-long marriage, reduce the perceived

rewards of marriage, and make children more reluctant to enter committed relationships (McRae, 1993; Amato 1996; Axinn and Thornton 1992; Axinn and Thornton 1996; Cui and Fincham 2010; Dronkers and Härkönen 2008). American research has also shown that parental experience of cohabitation, especially after divorce, is positively associated with adult children's own cohabitation, since they would have observed their parents choose this arrangement (Sassler et al 2009; Smock et al 2013).

4.1. MESO-LEVEL EXPLANATIONS AND MECHANISMS FROM QUALITATIVE RESEARCH

The intergenerational transmission of divorce to cohabitation emerged repeatedly throughout the focus groups. Individuals who experienced the divorce of their parents stated that they were unlikely to marry and would choose cohabitation instead. In eastern Germany, for example, one respondent bluntly stated, "I am a child of divorce, and that's the reason I don't want to marry." Participants in the other countries repeated this sentiment, acutely aware of the fragility of marriage because they had lived through the pain of their parents' divorce. In Poland, one woman said;

"I think it matters what children experienced at their own homes. I saw my parents getting divorced and I think that I won't get married, because what for? To get a divorce? I prefer to live the way I do now."

This idea that high divorce rates have made marriage less important was reiterated in a British focus group. The respondent does not reject the idea of a stable partnership, but instead the idea of marrying at all.

“Not just my parents but lots of my mates’ parents have got divorced and that, kind of, just makes me think, well, what’s the point? It’s more important to be with someone and stick with them than to get married.”

This participant in Austria, however, summarized how the intergenerational transmission of divorce may not necessarily lead to a complete rejection of marriage, but instead a delay of marriage, presumably in favor of cohabitation.

“...maybe our parents’ generation was the first generation where getting divorced was accepted and an option, and our generation is the first generation with many children of divorce. And maybe because of that, you have experienced it first hand or through your friends or acquaintances, and there is some reluctance to marry quickly.”

Thus, the previous sociological literature on the intergenerational transmission of family behaviors as well as the focus group discussions point to cohabitation as a way to cope with parental marital breakdown and the ensuing skepticism of marriage. Participants were aware that parental separation often leads individuals to reject the institution of marriage, or at the very least cohabit first to see whether their relationship will last. The qualitative research shows how attitudes, and indeed strong emotions, are an important mechanism in understanding the divorce-cohabitation link.

4.2. MESO-LEVEL ANALYSES WITH QUANTITATIVE DATA

To examine the divorce-cohabitation link at the meso-level, we use the Harmonized Histories to ascertain whether people whose parents separated or divorced are more likely to enter cohabitation for their first relationship compared to people whose parents remained married in childhood. In figure 2, we present the proportion of ever partnered women aged 20-49 in 2005

who started their first union with cohabitation by whether the parents lived together at age 15. This measure was obtained from a survey question that is relatively consistent across all the countries.⁴ As a check, we repeated the analyses for each 10-year age group and found the same relationship; hence the relationship is not due to the increase in both cohabitation and experience of parental separation across cohorts. We might hypothesize that the selectivity into cohabitation has reduced over historical time as cohabitation has become more normative. Ideally we would like to repeat our analyses for the same age group at an earlier period; however due to small sample sizes in most countries this was not possible.

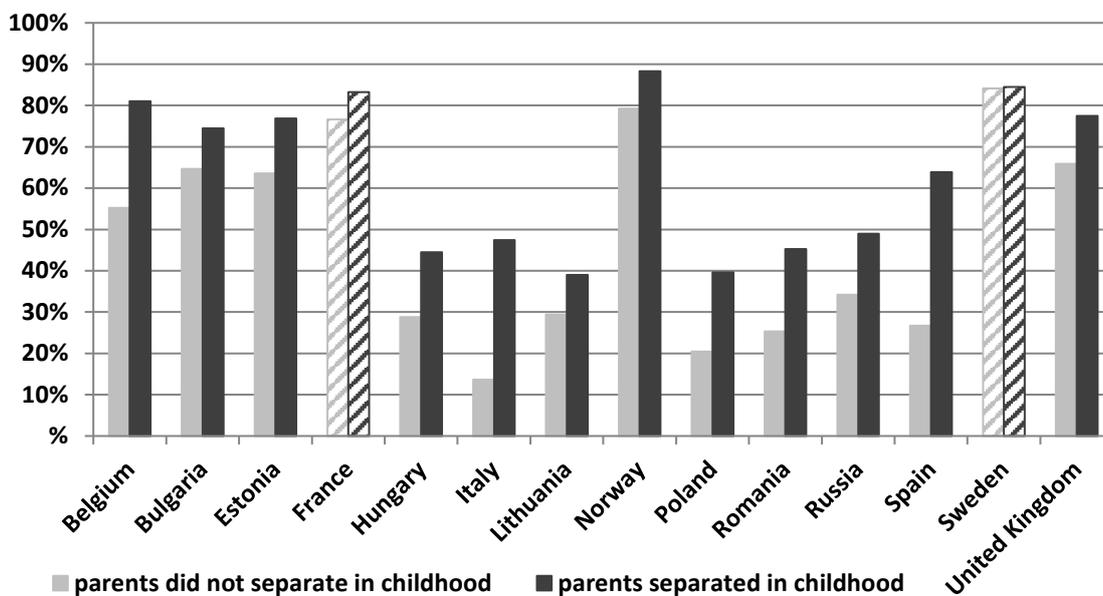

Figure 2: Percentage of ever partnered women aged 20-49, who started their first union with cohabitation, by parental union status at age 15 in 2005.

Notes: Solid bars indicate significant differences (non-overlapping confidence intervals) between parents' union status at age 15 for those whose first union type is cohabitation. Striped indicates no significant difference. Weights applied if available. Years of analysis may differ depending on survey.

⁴ In the UK, the question referred to age 16. The question was not asked in the Netherlands.

In all countries with the exception of Sweden, the proportion of women who began their first union with cohabitation was higher for those whose parents separated than those whose parents did not separate in 2005. The solid bars indicate that the difference in the two groups is significant (confidence intervals do not overlap) in all countries except France and Sweden (the shaded bars indicate an insignificant difference). In most countries, about 10% more women started their unions with cohabitation among those whose parents separated compared to those whose parents did not separate. The bars also indicate that direct marriage has remained more common among those whose parents stay married. In Sweden, France, and Norway, however, fewer than 25% of couples directly married, indicating that cohabitation is now the normative way of entering a co-residential partnership.⁵ Note that these indicators reflect the situation in 2005; the relationship between parental separation and cohabitation may have been significant earlier in the diffusion process in these countries. It is important to keep in mind the timing of divorce reform, which affects when the parents would have been able to divorce; in some countries, parents would not have been allowed to divorce. Thus, overall these results are consistent with the idea that the intergenerational transmission of parent's divorce to children's cohabitation is common across countries, and that intergenerational transmission can be considered a potential causal pathway helping to explain the link between divorce and cohabitation.

5. MICRO-LEVEL LINKS: INDIVIDUAL EXPERIENCE OF DIVORCE AND SUBSEQUENT COHABITATION

At the micro-level, an individual's own experience of divorce may lead him or her to be wary of marriage and prefer cohabitation for subsequent unions. People who had a bad experience with their first marriage may be more likely to live together without marrying than those who

⁵ Note that these results do not control for any potential covariates. Our data does not provide further detail about the parents' partnerships, including the experience of cohabitation or the formation of step-families.

were still influenced by the traditional norms of their families. Some researchers have posited that the increase in cohabitation occurred first among the previously married in their countries (e.g. Hungary (Spéder 2005); France (Villeneuve-Gokalp 1991), and the UK (Haskey 1994, Kiernan and Estaugh 1993, and Burgoyne 1991). This may especially be the case in countries with high divorce rates, but also in areas where marriage occurs at a young age, for example in countries east of Hajnal's line (Coale 1992). In Hungary, Spéder (2005) found that post-divorce cohabitation drove the spread of cohabitation, with pre-marital cohabitation only emerging since the 1980s. Researchers in other countries have also speculated that the rise in cohabitation began with the previously married, for example in France (Villeneuve-Gokalp 1991), and the UK (Haskey 1994, Kiernan and Estaugh 1993, and Burgoyne 1991).

5.1. MICRO-LEVEL EXPLANATIONS AND MECHANISMS FROM QUALITATIVE RESEARCH

In all countries, focus group participants discussed how their own personal experience of divorce led to skepticism about marriage and a preference for cohabitation in second unions. People who had divorced recounted their difficult experiences in the court systems, the expense, and bureaucratic frustrations. Their experiences often soured their opinion of marriage, as this Austrian woman stated;

“For me it [marriage] has become worthless. It has become like a piece of paper as I already had a divorce. I was expecting more, but in reality a credit agreement is worth more than the marriage certificate. Because it binds for a longer time than marriage.”

This Russian woman also expressed her reluctance to remarry and preference for cohabitation:

“My husband was the initiator of divorce. I wish him to be happy. I have a second union, too. I am happy. I am satisfied. I have been with this second man for two years; I like him. But I am not in a hurry to marry him, because my first marriage ended in divorce.”

And this Dutch woman recounted her negative experience with divorce:

“I have just learned that a lot of things can go wrong by getting married. Because then it is no longer your things, but your joint things. And when he does something wrong, you automatically do something wrong. Debts, for instance, that will then also be your responsibility, and may stay your responsibility even when you are divorced.”

Hence, personal experience of divorce often produces a dislike of the institution of marriage and choice of cohabitation for second unions and raises the question of whether cohabitation may have emerged first among those who experienced divorce.

5.2. MICRO-LEVEL ANALYSES WITH QUANTITATIVE DATA

Cross-national quantitative research shows that in many countries of Europe, second unions are more likely to start with cohabitation than marriage, even in countries with a low prevalence of cohabitation (Galezewska et al 2016). These findings provide evidence that cohabitation is indeed the preferred type of union for those who have already experienced marriage and are at risk of repartnering. Here, however, we provide a different perspective by focusing on the composition of cohabiting couples: we are interested in whether the majority of cohabiting couples have previously divorced or are never married. By tracing the changing composition of cohabiting couples over time, we can ascertain to what extent divorced individuals were the forerunners in the cohabitation boom.

--- never married —●— divorced — widows

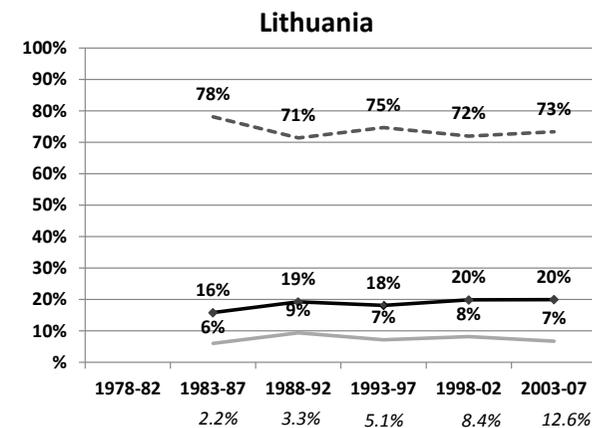

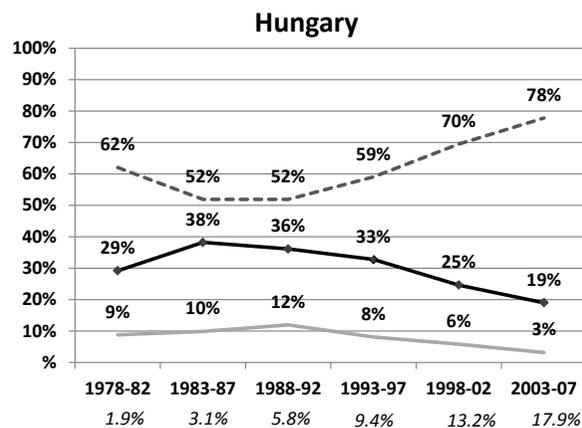

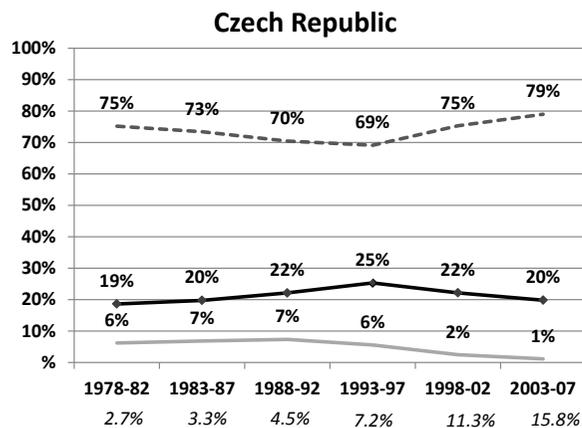

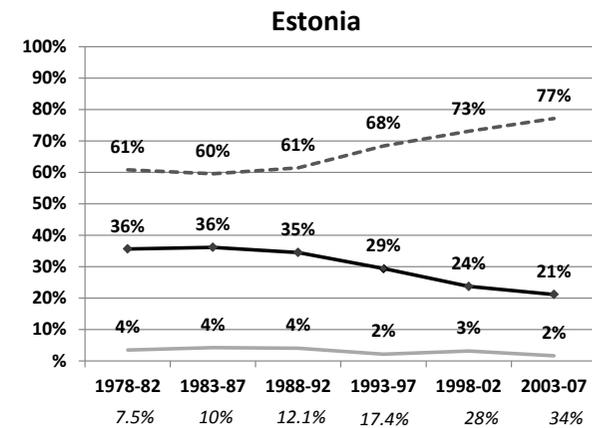

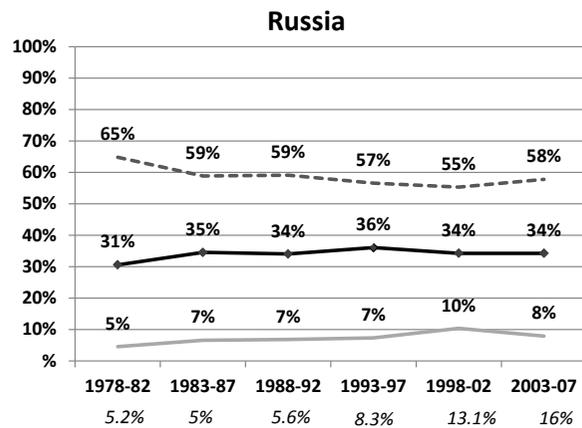

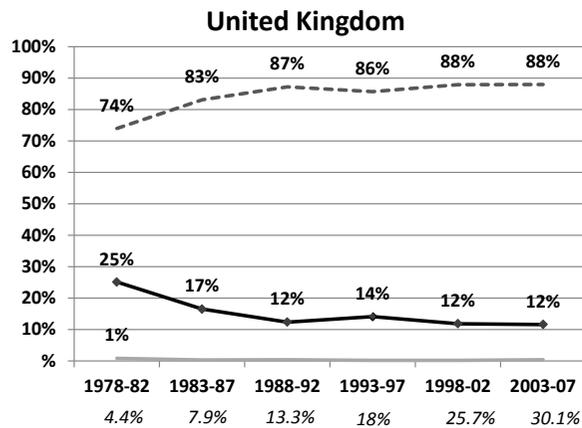

Figure 3a: Percentage of never married, divorced and widowed currently cohabiting women among all currently cohabiting women aged 20-49. Group a: Divorce initially high and steadily increasing - Cohabitation initially low, then increasing at faster pace than divorce.

Note: Below the X-axis in parentheses we include the weighted percentage of currently cohabiting women among women in a couple based on 5-years of data.

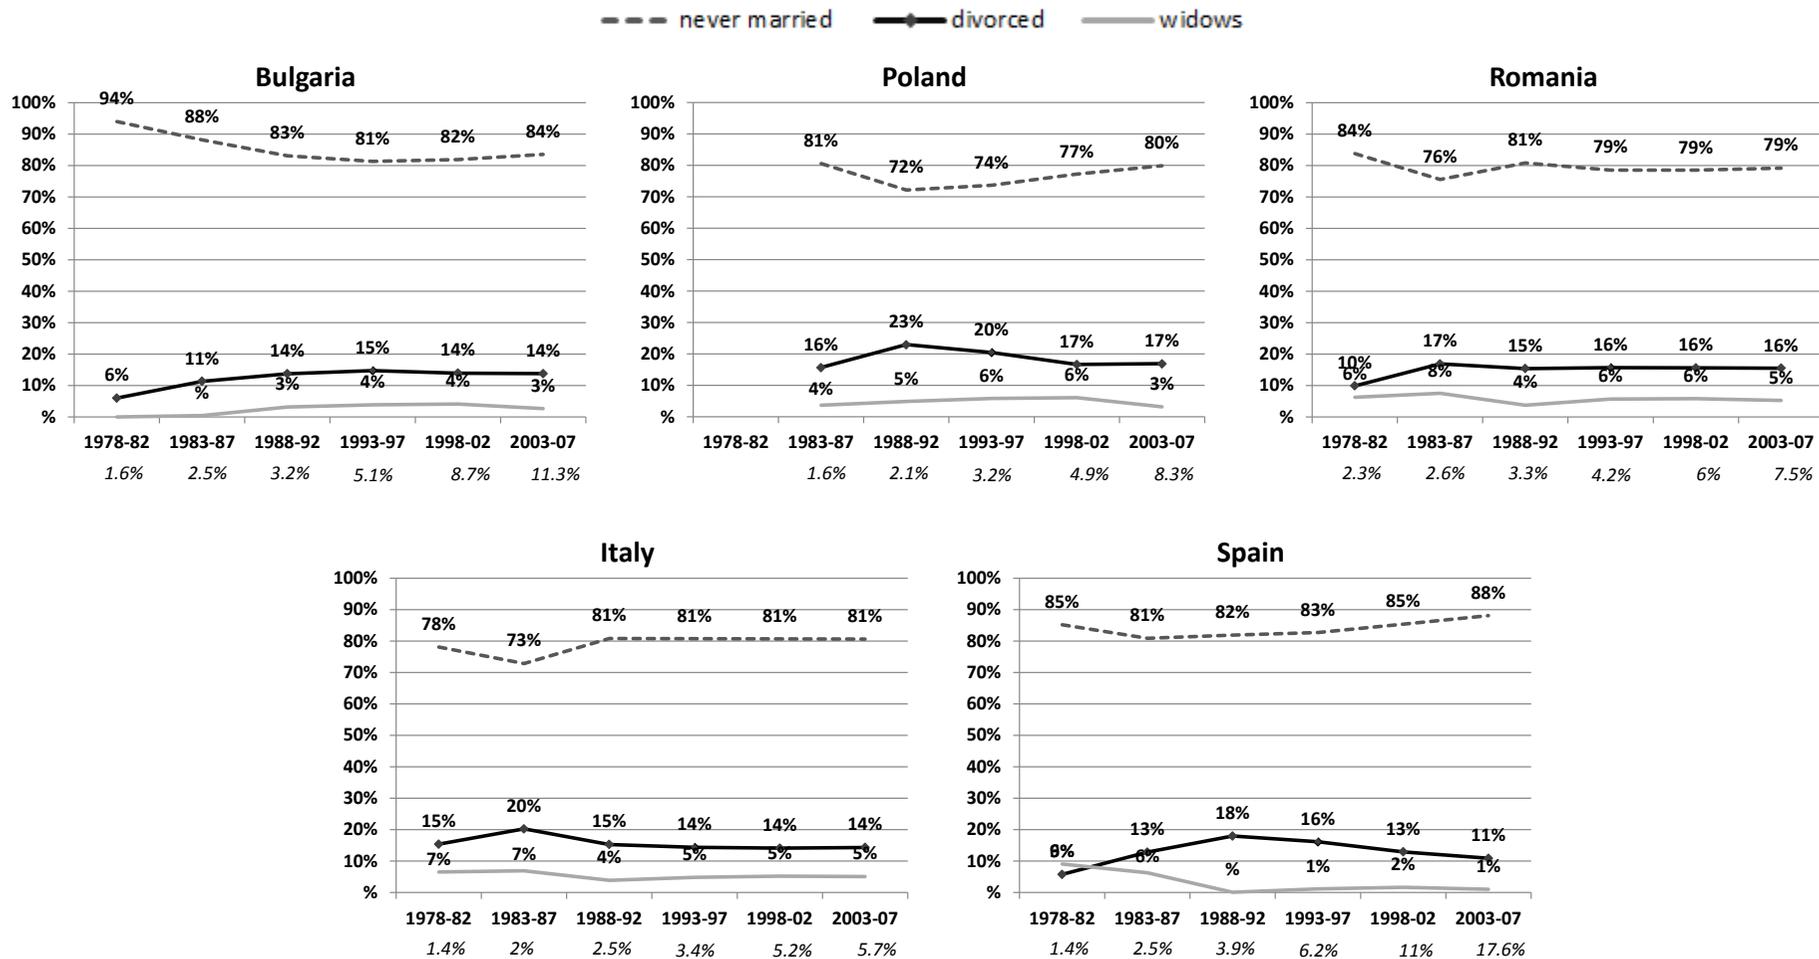

Figure 3b: Percentage of never married, divorced and widowed currently cohabiting women among all currently cohabiting women aged 20-49. Group b: Divorce initially low, then slowly increasing – Cohabitation initially low, increasing since 1990s/2000s.

Note: Below the X-axis in parentheses we include the weighted percentage of currently cohabiting women among women in a couple based on 5-years of data.

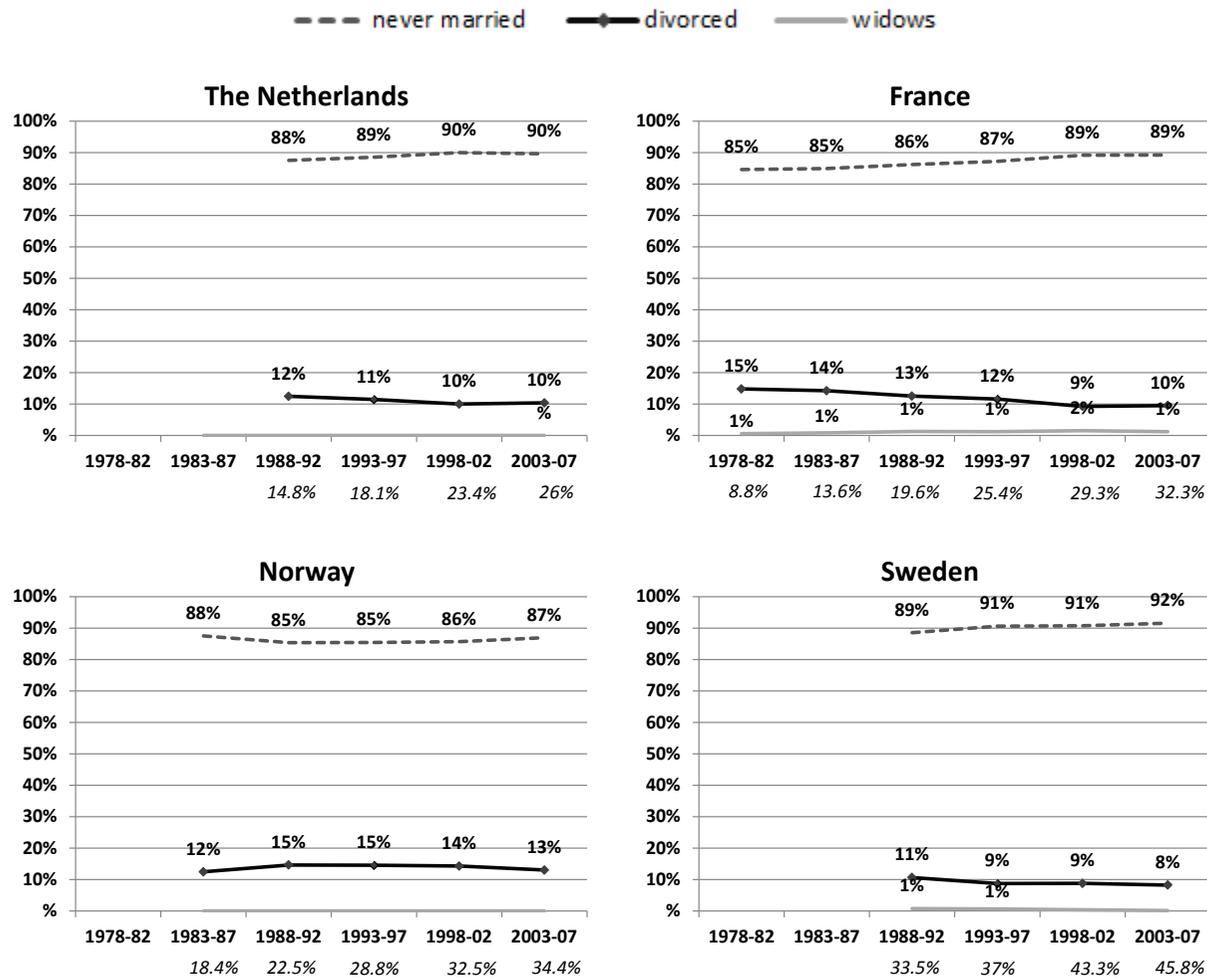

Figure 3c: Percentage of never married, divorced and widowed currently cohabiting women among all currently cohabiting women aged 20-49. Group c: Divorce and cohabitation initially as similar levels – Cohabitation then outpacing divorce.

Note: Below the X-axis in parentheses we include the weighted percentage of currently cohabiting women among women in a couple based on 5-years of data.

Figures 3a-3c show the percentage of never married, divorced, and widowed women aged 20-49 among all those who are currently cohabiting in a given five-year time period for each country. The solid lines represent the never married; the dashed lines represent the previously married, and the dash-dot-dash lines represent the widowed women. The percentages for five-year time periods range backwards in time as far as the data will allow.⁶ We also show the percent of all women in a union who were cohabiting below the estimates to provide a sense of the magnitude of the behavior. In order to correspond to the macro-level results, we organized the figures according to the groups shown in Figures 1a-1c.

Overall, the figures show that in any given time period, a relatively small percentage of cohabitators were previously married; most were never married. In nearly every country, over 75% of those cohabiting were never married. For the most part, contrary to our hypothesis, cohabitation seems to have increased more among the never married than the divorced. Nonetheless, in Hungary, Russia, and Estonia over a third of women cohabiting ever experienced divorce in some of the periods of observation (Figure 3a). As discussed above, many former socialist countries had a relatively young age at first marriage and high levels of divorce, providing a larger group exposed to repartnering. These divorced women may have broken with strong marriage tradition and cohabited rather than married. Hence, post-marital cohabitation may have played a substantial role in the increase in cohabitation in these countries.

Other countries may also have experienced a higher proportion of previously married women cohabiting when cohabitation was just starting to become widespread. The UK, for

⁶ The percent of currently cohabiting women in each marital status is based on five years of data to increase sample size; we only included data points with more than 100 cohabitators. The calculations have been centered around the mid-point of the five year age group (i.e. 1980) by averaging 5 years of information collected in January of each year. Belgium was not included as sufficient data is only available from 1994.

example, had a greater proportion of cohabitators who had divorced when cohabitation was just starting to increase (Figure 3a). In 1978-82, 25% of women cohabiting had previously divorced, suggesting that the initial increase in cohabitation may have been led by the newly divorced. Subsequently, the relative percent who had divorced declined, with those who had never married a much greater proportion of those currently cohabiting. This decline seems to have occurred in most other countries as well, or more commonly, the percent of the divorced relative to the never married stayed relatively stable, at around 15%. Partially this may be due to the age range analyzed; our analyses only capture women up to age 49, and cohabitation among the previously married may have initially increased more at older ages. Note also that we do not have early estimates for Norway, Sweden, and the Netherlands, when cohabitation was practiced by less than 15% of the population. In general, however, with the exception of the UK, Hungary, Russia, and Estonia, these figures suggest that the divorced were not the primary forerunners of cohabitation, although they may have played a small role in the increase as cohabitation began to diffuse.

6. CONCLUSIONS

Throughout the industrialized world, divorce and cohabitation rapidly emerged from the 1970s onwards, buoyed by a wave of social, economic and ideational change. Although exogenous factors such as rising female employment and ideational change no doubt play a strong role in spurring these changes, divorce and cohabitation also seem to be increasing through interactions with each other – in particular, divorce seems to be exacerbating the increase in cohabitation. In this article, we explored explanations and mixed methods evidence for this link on the macro-, meso-, and micro-levels. We now synthesize this evidence and provide an argument for why the divorce revolution may be linked to the cohabitation boom.

First, on the macro-level, the diffusion of attitudes and norms about divorce and marriage may have been one of the key causal pathways leading to the increase in cohabitation. The focus group research suggests that Europeans are cognizant of the consequences of divorce and that divorce may discourage people from marrying, or at least marrying quickly and without ensuring that the relationship is solid. Participants mentioned that cohabitation is a way to test the relationship in order to avoid the costs of divorce, which were described as almost always higher than the costs of cohabitation dissolution. In fact, some participants bitterly complained about the high costs of divorce, saying that they refused to marry and recommending that others not marry, especially men, who could suffer negative economic consequences. For these participants, cohabitation was seen as a favorable alternative to marriage. Most participants, however, did not eschew marriage altogether and planned to marry in the future; for them, cohabitation was seen as a way to make sure their relationship was strong enough to get married.

Our quantitative macro-analyses partially supported this diffusion argument. In all countries observed, the increase in divorce behavior, as well as divorce law reform, occurred before or simultaneously with the increase in cohabitation, indicating the appropriate temporal ordering for causality, although direct causality is impossible to determine from our analyses. The magnitude of the increase and the strength of the link, however, differed across countries. In some countries, such as the UK, Russia, Estonia, Lithuania, and Hungary, divorce was widespread before cohabitation, suggesting that high levels of divorce may have changed social norms and attitudes about the institution of marriage. In France, on the other hand, the general experience of ever divorcing increased relatively slowly, while cohabitation expanded rapidly, suggesting that other important factors led to the diffusion of cohabitation, for example the rejection of the institution of marriage associated with the Catholic Church or changes in

single-mother policies (Knijn et al. 2007). In other countries such as Belgium, the Netherlands, Norway, and Sweden, divorce increased rapidly from the 1970s, but the data cannot tell the extent to which the increase in divorce preceded the increase in cohabitation. Nonetheless, in most of our countries, divorce seems like a necessary but insufficient cause for cohabitation to diffuse, and the explanations for the increase in cohabitation may be context specific.

On the meso-level, a substantial amount of evidence suggests that the link between divorce and cohabitation was driven by the intergenerational transmission of attitudes and behavior. Parental divorce emerged repeatedly in the focus group discussions, with the children of divorced couples often blunt in their rejection of marriage, or at least direct marriage. This finding was reflected in the quantitative analyses: the respondents whose parents separated during their childhood were significantly more likely to choose cohabitation for their first union than those whose parents stayed together, with the exception of France and Sweden, where nearly everyone enters cohabitation rather than directly marrying. These results suggest that on the meso-level, the diffusion of cohabitation occurred through the process of social learning: as individuals observed the breakdown of their parents' relationship, they may have adopted conflict behaviors and attitudes that led them to be more skeptical of marriage and committed relationships in general (Cui and Fincham 2010; Axinn and Thornton 1996). These individuals may then have preferred cohabitation as an alternative living arrangement, allowing them to live with a partner without committing to a more permanent relationship. All in all, our findings suggest that social learning from parents was one of the most important pathways for the diffusion of cohabitation.

We also found evidence on the micro-level indicating that divorced individuals may prefer to cohabit when repartnering, because of their negative personal experience with

marriage. The tendency to choose cohabitation after divorce was a widespread theme in our focus group research. Most divorced individuals expressed a very low opinion of marriage and a reluctance to marry again. Previous quantitative research supports these assertions by showing that throughout Europe, second and higher-order unions are much more likely to start with cohabitation than direct marriage and the propensity to cohabit is greater among the previously married than the never married (Galezewska et al 2016). Overall, these findings indicate that the institutional constraints of marriage and high costs of divorce dissuade people from marrying, but not necessarily repartnering in cohabitation. Nonetheless, the quantitative analyses in our study showed that the previously married did not appear to be the forerunners of cohabitation in most countries. A group of countries with relatively high divorce rates – Russia, Hungary, and Estonia - showed a higher percent of divorced women among those cohabiting in some periods, but the percent was never greater than 36%, suggesting that even in these countries cohabitation increased primarily among the never married. Even so, while the overall increase in cohabitation may have been driven by the never married rather than the divorced, the role of cohabitation for those who did divorce could still have been very important: individual experiences of divorce may have influenced others' perspectives on marriage and revealed the advantage of cohabitation before marriage.

This project is a first step to understanding whether and how divorce and cohabitation are related, and it has several limitations. The qualitative research had broad coverage by being conducted in eight countries in Europe, but it was not conducted in all of our study countries with quantitative data, and clearly does not reflect all European diversity. It would be particularly interesting to see whether divorce is an important theme in Sweden and France or if other explanations for the increase in cohabitation predominate. Also, several of our hypotheses are implicitly about the initial rise in cohabitation, and we cannot go back in time

to explore norms and attitudes when cohabitation was just beginning to emerge. This is also the case for our quantitative analyses: to our knowledge, data on cohabitation in the 1970s and 80s does not exist for several of our countries, so we cannot know for sure whether divorce or cohabitation emerged first. Finally, our analyses are relatively simple without co-variables or controlling for selection effects which may be very important for revealing confounders or explaining differences across countries. Our goal was to provide a broad, descriptive overview, but further, more sophisticated analyses may provide more robust evidence for or against a causal link.

In conclusion, the study provides fundamental insights into how divorce has shifted social norms and facilitated the increase in cohabitation to become an alternative way of living with a partner. At the micro-level, personal experience with divorce was key to understanding the preference for cohabitation; previous findings (Galezewska et al. 2016) show that those who experience divorce are more likely to choose cohabitation for second partnerships to avoid another unsuccessful marriage. In some countries the previously married were an important minority of those cohabiting, and their act of divorcing would have raised doubts about the marital institution for everyone. Nonetheless, the increase in cohabitation was driven more by the never married than the previously married. At the meso-level, the intergenerational transmission of behaviors through social learning was especially important: individuals whose parents divorced learned about the drawbacks of marriage and subsequently may have preferred cohabitation to avoid similar pitfalls. On the macro-level, social norms and attitudes about marriage shifted and the appeal of cohabitation increased as a way to test the relationship or avoid marriage altogether. Thus, while other exogenous factors may also have been important for the increase in cohabitation, the divorce revolution, with its concomitant shifting

of social norms and perceptions about marriage, may well have been a crucial catalyst for the cohabitation boom.
